

O(1) Time Complexity

O(1) Time Complexity (Constant Time) means that the execution time of an operation does **not** depend on the size of the input (n).

No matter how large the data is, the time taken remains the same.

example:-

```
my_list = [10, 20, 30, 40, 50]

print(my_list[2])
```

Accessing my_list[2] always takes the same time, whether the list has 5 elements or 5 million.

Variable assignment:-

```
x = 10
```

Arithmetic operation:-

```
x = 10
```

Dictionary (hash table) access:-

```
x = 10
```

Accessing first or last element:-

```
my_list = [10, 20, 30, 40]

print(my_list[0])    # first element
print(my_list[-1])   # last element
```

Checking length of list:-

```
my_list = [10, 20, 30, 40]

print(len(my_list))
```
